then, letting  $(.) =$ , the equation for Crank-Nicolson method is a combination of the forward Euler method at  $n$  and the backward Euler method at  $n + 1$  (note, however, that the method itself is not simply the average of those two methods, as the backward Euler equation has an implicit dependence on the solution):

Crank Nicolson Scheme for the Heat Equation. The goal of this section is to derive a 2-level scheme for the heat equation which has no stability requirement and is second order in both space and time. From our previous work we expect the scheme to be implicit.

I am trying to solve the 1D heat equation using the Crank-Nicholson method. I have managed to code up the method but my solution blows up. I'm using Neumann conditions at the ends and it was advised that I take a reduced matrix and use that to find the interior points and then afterwards.

Crank-Nicolson method. An important question is to establish a maximum principle for the approximations obtained with the Crank-Nicolson method, similar to the one satisfied by the solutions of the heat equation. Related topics are monotonicity properties and, in particular, the non-negativity (or non-positivity) of the numerical approximations.

Python implementation of Crank-Nicolson scheme. As time progresses, the two "heat sources" (or sinks) at the sides are kept at constant low temperature. The diffusion of heat results in the rod becoming colder and colder until its temperature becomes equal to the temperature at the boundaries.

Numerical calculation performed using  $\Delta t$ ,  $\Delta x$ , and  $\Delta y$ . The solid curve shows the initial condition at  $t=0$ , the short-dashed curve the numerical solution at  $t=\Delta t$ , the long-dashed curve the numerical solution at  $t=2\Delta t$ , and the dot-dashed curve the numerical solution at  $t=3\Delta t$ .
